Abstract

Stemwood cubic-foot volume inside bark tables are presented for 16 species and 8 species groups based on equations used to estimate timber sale volumes on national forests in the Piedmont. Tables are based on form class measurement data for 2,753 trees sampled in the Piedmont and taper data collected across the South. A series of tables is presented for each species based on diameter at breast height (d.b.h.) in combination with total height and height to a 4-inch diameter outside bark (d.o.b.) top. Volume tables are also presented based on d.b.h. in combination with height to a 7-inch d.o.b. top for softwoods and height to a 9-inch d.o.b. top for hardwoods. Sawtimber tables display saw-log stem volume by log (16-foot) and half-log (8-foot) intervals and also show stemwood volume to a 7-inch d.o.b. top for softwoods, to a 9-inch d.o.b. top for hardwoods, and to a 4-inch d.o.b. top for all species. Pulpwood tables show stemwood volume to a 4-inch d.o.b. top in 5-feet height intervals.

Keywords: Saw-log volume, pulpwood volume, form class.

Introduction

Purpose and Scope

Starting in 1995, the standard unit of measure for Federal timber inventories and sales will be the cubic foot rather than the board foot. This change is necessary to provide uniform inventory, accounting, and statistical reporting for all national forests. To accommodate this change in the Southern Region of the USDA Forest Service, Clark and others (1991) developed new equations for converting height and diameter measurements into cubic-foot volume estimates. Because they reflect variations in tree form and taper, the new equations are awkward to solve without a computer. For those who lack the time to solve the equations manually and the equipment expertise for electronic processing, conversion tables have been developed to provide volume estimates for 16 individual species and for 8 species groups that have similar stem form. The tables are based on form class measurement data collected on trees sampled in the Piedmont and taper data collected on trees sampled across the South.

The Southern Region consists of seven geographic areas (fig. i) based on physiographic region, species form and distribution, and Forest Service administrative units (table i). Table ii lists the species and geographic areas for which volume tables are available, and table iii summarizes measurement characteristics of the trees sampled.

A separate set of volume tables is available for many of the species and species groups in other geographic areas of the Southern Region (Clark and Souter 1996a, 1996b, 1996c, 1996d, 1996e, 1996f). When a species volume table for a species measured in the Piedmont is not available the Southwide tables should be used (Clark and Souter 1994).

Development of Equations

The volume tables in this paper are based on profile equations developed from taper data collected on 13,469 trees sampled in natural stands across the South. Most of the trees measured were on national forests. All were growing in fully stocked stands. The taper data used to develop and verify the profile equations were collected on 11,472 trees by contractors working for the Southern Region and on 1,997 trees by employees of the Forest Service, Southeastern Forest Experiment Station¹, SE-4701, Utilization of Southern Timber.

Sample trees were felled and their diameter at breast height (d.b.h.) and total height recorded. The contractors measured diameter outside bark (d.o.b.) and bark thickness at stump height and at 1-inch taper intervals from the stump to the tip of the tree. Diameters were measured with a diameter tape and bark thickness determined at two points with a bark gauge at each measurement height. Trees sampled by the Southeastern Station were measured at groundline, 1 and 2 feet, breast height, and at intervals of approximately 4 feet above breast height. Bark thickness was determined from cross-sectional disks cut from the boles.

¹ Now called the Southern Research Station.

^{a b} Number of sample trees do not add to species group totals because some species are included in the total but were not sampled sufficiently to develop individual species equations.

Clark and others (1991) compared available segmented-profile polynomial models (Max and Burkhart 1976; Cao and others 1980; Schlaegel 1983) as potential volume estimators for southern tree species. Because no one model was best for estimating stem volume from the diameter and height of standing trees, they developed a form-class segmented-profile model that uses d.b.h., diameter at 17.3 feet, and total height as independent variables and that combines the better attributes of Schlaegel's form-class model and Max and Burkhart's segmented-profile model. The new model divides the stem into four segments--butt (groundline up to 4.5 feet), lower stem (4.5 up to 17.3 feet), middle stem (17.3 to 40 up to 70 percent of total height), and upper

stem (40 to 70 percent of total height up to stem tip) and uses different equation form to estimate diameter, height, and volume for each segment. The segment equations are conditioned so that the joins between segments are continuous. Separate profile equations incorporate height to a 4-inch d.o.b. top for all species, and height to a 7-inch d.o.b. top for softwoods, or height to a 9-inch d.o.b. top for hardwoods.

The form-class segmented-profile model can be used to predict diameter at a known height, height to a known diameter, and volume between any two heights. The equation forms and coefficients for estimating diameters, heights, and volumes are presented in Clark and others (1991).

The profile equations account for differences in stem taper by including a measure of diameter inside bark (d.i.b.) at 17.3 feet or Girard Form Class² in each volume estimate, thus, allowing a single form-class segmented-profile equation to serve for a species across the South. However, analysis of the form-class data showed geographic differences in the form class of sawtimber trees with the same d.b.h. and height. Thus, linear equations for estimating d.i.b. at 17.3 feet were developed for each species and species group by geographic region. Equations were developed to estimate d.i.b. at 17.3 feet from d.b.h. and total height, from d.b.h. and height to a 4-inch d.o.b. top, and from d.b.h. and height to a 7-inch or 9-inch d.o.b. top. Because few short pulpwood trees were sampled, an average form class by species group and d.b.h. and height class was used when predicting stemwood volume of pulpwood trees \leq 45 feet in total height or \leq 30 feet in height to a 4-inch d.o.b. top.

Although the profile equations based on total height can be applied to any trees having both d.b.h. \geq 5.0 inches and total height $>$ 17.3 feet, the total height tables in this book start at 30 feet. The profile model based on d.b.h. and height to a Q-inch d.o.b. top can be applied to any tree with d.b.h. \geq 5.0 inches and height to a 4-inch d.o.b. top $>$ 17.3 feet, but the tables based on height to a 4-inch d.o.b. top start at 20 feet.

The softwood profile equation based on d.b.h. and height to a 7-inch d.o.b. top is only useful if the trees have a d.b.h. \geq 9.0 inches, and their height to a 7-inch d.o.b. top $>$ 17.3 feet. The hardwood equation based on d.b.h. and height to a 9-inch d.o.b. top can only be applied to trees with d.b.h. \geq 11.0 inches, whose height to a 9-inch d.o.b. top $>$ 17.3 feet. However, the softwood and hardwood tables based on height to a 7-inch or 9-inch d.o.b. top, respectively, start at 20 feet.

² Girard Form Class is the ratio of d.i.b. at 17.3 feet from d.b.h.

The form-class segmented-profile equation based on height to a 7-inch or 9-inch d.o.b. top can only estimate diameters, heights, or volumes from the groundline to these top heights. Therefore, Clark and others (1991) developed nonlinear ratio equations for estimating volume between the 7-inch or 9-inch d.o.b. top and the 4-inch d.o.b. top. They developed topwood ratio equations for each commercially important species by geographic area and for each species Southwide.³

How To Use Volume Tables

Content and Organization

For each species or species group, this book presents **stemwood** volume in a series of five tables based on varying combinations of d.b.h. and height. The first shows volume for sawtimber trees based on d.b.h. and total height. The second shows volume for sawtimber trees based on d.b.h. and height to a 4-inch **d.o.b.** top. The third shows volume for sawtimber trees based on d.b.h. and height to a 7-inch **d.o.b.** top for softwoods or height to a **9-inch d.o.b.** top for hardwoods. The fourth shows volume for pulpwood trees based on **d.b.h.** and total height. The fifth shows pulpwood volume based on **d.b.h.** and height to a 4-inch **d.o.b.** top. Each sawtimber table displays volume for softwoods (10-inches to 24-inches **d.b.h.**) and hardwoods (**12-inches** to 26-inches **d.b.h.**) in 16-foot log or in 8-foot half-log intervals in 2-inch **d.b.h.** classes. The saw-log volume tables also show **average** form class and volume to a 4-inch **d.o.b.** top, and to a 7-inch **d.o.b.** top for softwoods or to a **9-inch d.o.b.** top for hardwoods. The pulpwood tables show volume to a 4-inch **d.o.b.** top for trees 5-inches to 16-inches **d.b.h.** in 5-foot height intervals and in 1-inch **d.b.h.** classes.

Finding Volume Estimates

To use these tables you must know the species or species group, **d.b.h.**, and an expression of height. You can look up **stem volume** based on total height or height to a 4-inch **d.o.b.** top for pulpwood; based on total height, or height to a **4-inch d.o.b.** top for sawtimber; or based on height to a 7-inch **d.o.b.** top for softwood **sawtimber** or height to a **9-inch d.o.b.** top for hard-wood sawtimber. For sawtimber trees, you must also know the height to the saw-log

merchantable⁴ top in logs and in half logs. For example, to determine the saw-log and **topwood** volume for an 18-inch, 3-log loblolly pine with a height to a 7-inch **d.o.b.** top of 60 feet, refer to the Index of Volume Tables (page 3) for the table number of the loblolly pine volume table based on **d.b.h.** and height to a 7-inch **d.o.b.** top (table 18). In table 18 locate the volume data for an 18-inch **d.b.h.** tree with a height to 7-inch top of 60 feet. If you look across this row you will find the **saw-log** volume under a 3-log merchantable stem (48.2 cubic feet). This same row also shows stem volume to a 7-inch and a 4-inch **d.o.b.** top and the estimated Girard Form Class of the tree. To estimate the volume of **topwood** between the saw-log merchantable top and 4-inch **d.o.b.** top, subtract the saw-log volume (48.2 cubic feet) from the volume to a 4-inch **d.o.b.** top (53.4 cubic feet) for a result of 5.2 cubic feet.

If you do not know the height to a given top (total height, height to a 4-inch top, or height to a 7-inch or **9-inch top**) for a sawtimber tree, you can use the total height tables for a rough estimate of volume, but only if you know the **d.b.h.** and saw-log merchantable height and have an estimate of Girard Form Class. Form class can be the species average for the geographic area from table III or the species average for the area in which the tree is growing. For example, to determine the saw-log volume of a 14-inch shortleaf pine with a saw-log merchantable height of 2.5 logs, refer to the Index of Volume Tables to find the table number for shortleaf pine based on **d.b.h.** and total height (table 6).

⁴ Saw-log merchantable height is (1) the height to local minimum **d.o.b.** top, or (2) the height where a whorl of three or more branches-whose diameters are equal to or greater than the diameter of the stem-occurs within a 1 -foot stem section if there is not a minimum of 8 feet of clear stem above the whorl.

Assume the average form class for shortleaf pine in the area the tree was growing is 80. In table 6, locate the volume data for merchantable stem and find the tree's saw-log merchantable volume for a **14-inch d.b.h. tree with a form class of 80**. Look across the row for the saw-log volume under a merchantable 2.5-log stem (26.2 cubic feet).

To determine the stem pulpwood volume of an 8-inch d.b.h. southern red oak with a height to a 4-inch d.o.b. top of 50 feet, refer to the Index of Volume Tables for the table number based on d.b.h. and height to a 4-inch top (table 95). In table 95, locate the volume data for an 8-inch d.b.h. tree with a height to a 4-inch top of 50 feet and find the tree's volume (8.7 cubic feet).

Clark, Alexander III; Souter, Ray A. 1996. Stem cubic-foot volume tables for tree species in the Piedmont. Res. Pap. SE-295. Asheville, NC: U.S. Department of Agriculture, Forest Service, Southern Research Station. 109 p.

Stemwood cubic-foot volume inside bark tables are presented for 16 species and 8 species groups based on equations used to estimate timber sale volumes on national forests in the Piedmont. Tables are based on form class measurement data for 2,753 trees sampled in the Piedmont and taper data collected across the South. A series of tables is presented for each species based on diameter at breast height (d.b.h.) in combination with total height and height to a Cinch diameter outside bark (d.o.b.) top. Volume tables are also presented based on d.b.h. in combination with height to a 7-inch d.o.b. top for softwoods and height to a 9-inch d.o.b. top for hardwoods. Sawtimber tables display saw-log stem volume by log (16-foot) and half-log (8-foot) intervals and also show stemwood volume to a 7-inch d.o.b. top for softwoods, to a 9-inch d.o.b. top for hardwoods, and to a 4-inch d.o.b. top for all species. Pulpwood tables show stemwood volume to a Cinch d.o.b. top in 5-feet height intervals.

The Forest Service, U.S. Department of Agriculture, is dedicated to the principle of multiple use management of the Nation's forest resources for sustained yields of wood, water, forage, wildlife, and recreation. Through forestry research, cooperation with the States and private forest owners, and management of the National Forests and National Grasslands, it strives-as directed by Congress-to provide increasingly greater service to a growing Nation.
